

Electronic Spectroscopy of molecules

Part I: Frank-Condon Principle

B.Sc. (H) Chemistry

Objective of the Electronic Spectroscopy

- Many of the colours of the objects in the world around us arises from transitions in which an electron is promoted from one orbital of a molecule or ion into another.
- Some cases the relocation of an electron may be so extensive that it results in the breaking of a bond and the initiation of a chemical reaction.
- To understand these physical and chemical phenomena, We need to explore the origins of electronic transitions in molecules.

Molecular Energy Levels

The Born-Oppenheimer Approximation

The electronic, vibrational, and rotational energies of a molecule are completely independent of each other.

$$E_{total} = E_{electronic} + E_{vibration} + E_{rotation}$$

$$\Delta E_{tot.} = \Delta E_{elec.} + \Delta E_{vib.} + \Delta E_{rot.} \quad \text{Joule}$$

$$\Delta \varepsilon_{tot.} = \Delta \varepsilon_{elec.} + \Delta \varepsilon_{vib.} + \Delta \varepsilon_{rot.} \quad \text{cm}^{-1}$$

- *Vibrational changes* will produce a '**coarse structure**' and *rotational changes* a '**fine structure**' on the spectra of electronic transitions.
- Unlike Pure rotational and vibrational spectroscopy where dipole moment and dipole moment change is required, electronic spectra are given by all molecules since changes in the electron distribution in a molecule are always accompanied by a dipole change.

Vibrational Coarse Structure: Progressions

For coarse vibrational spectra, rotational changes could be ignored

$$\epsilon_{tot.} = \epsilon_{elec.} + \epsilon_{vib.} \quad cm^{-1}$$

There is essentially no selection rule for ν when a molecule undergoes an electronic transition.

Transitions are conventionally labelled according to their (ν', ν'') numbers (note: upper state first), that is $(0, 0)$, $(1, 0)$, $(2, 0)$, etc.

Such a set of transitions is called a band since, under low resolution, each line of the set appears somewhat broad and diffuse, and is more particularly called a ν' progression, since the value of ν' increases by unity for each line in the set.

Vibrational Coarse Structure: Progressions

$$\Delta E_{tot.} = \Delta E_{elec.} + \Delta E_{vib.} \text{ Joule}$$

$$\Delta \varepsilon_{tot.} = \Delta \varepsilon_{elec.} + \Delta \varepsilon_{vib.}$$

$$\begin{aligned} \bar{\nu}_{spec.} = & (\varepsilon' - \varepsilon'') + \left\{ (v' + \frac{1}{2})\bar{\omega}'_e - x'_e(v' + \frac{1}{2})^2\bar{\omega}'_e \right\} \\ & - \left\{ (v'' + \frac{1}{2})\bar{\omega}''_e - x''_e(v'' + \frac{1}{2})^2\bar{\omega}''_e \right\} \quad \text{cm}^{-1} \end{aligned}$$

$\bar{\omega}'_e, \bar{\omega}''_e, x'_e$ and $x''_e =$ Can be calculated

Morse Potential Curve in electronic transitions

- Classical and quantum theory both suggest that the oscillating atom would spend most of its time *on* the curve at the turning point of its motion, since it is moving most slowly there, i.e, at the extremities.
- Quantum theory, shows that for $v = 0$ the atom is most likely to be found at the *centre* of its motion, i.e. at the equilibrium internuclear distance r_{eq} .

The Franck-Condon Principle

Franck-Condon principle states that an electronic transition takes place so rapidly that a vibrating molecule does not change its internuclear distance appreciably during the transition.

If a diatomic molecule undergoes a transition into an upper electronic state in which the excited molecule is stable with respect to dissociation into its atoms, then we can represent the upper state by a Morse curve similar in outline to that of the ground electronic state

We should consider each excited molecule as a new, but rather similar, molecule with a different, but also rather similar, Morse curve because the vibrational frequency, internuclear distance, anharmonicity constants and dissociation energies may differ.

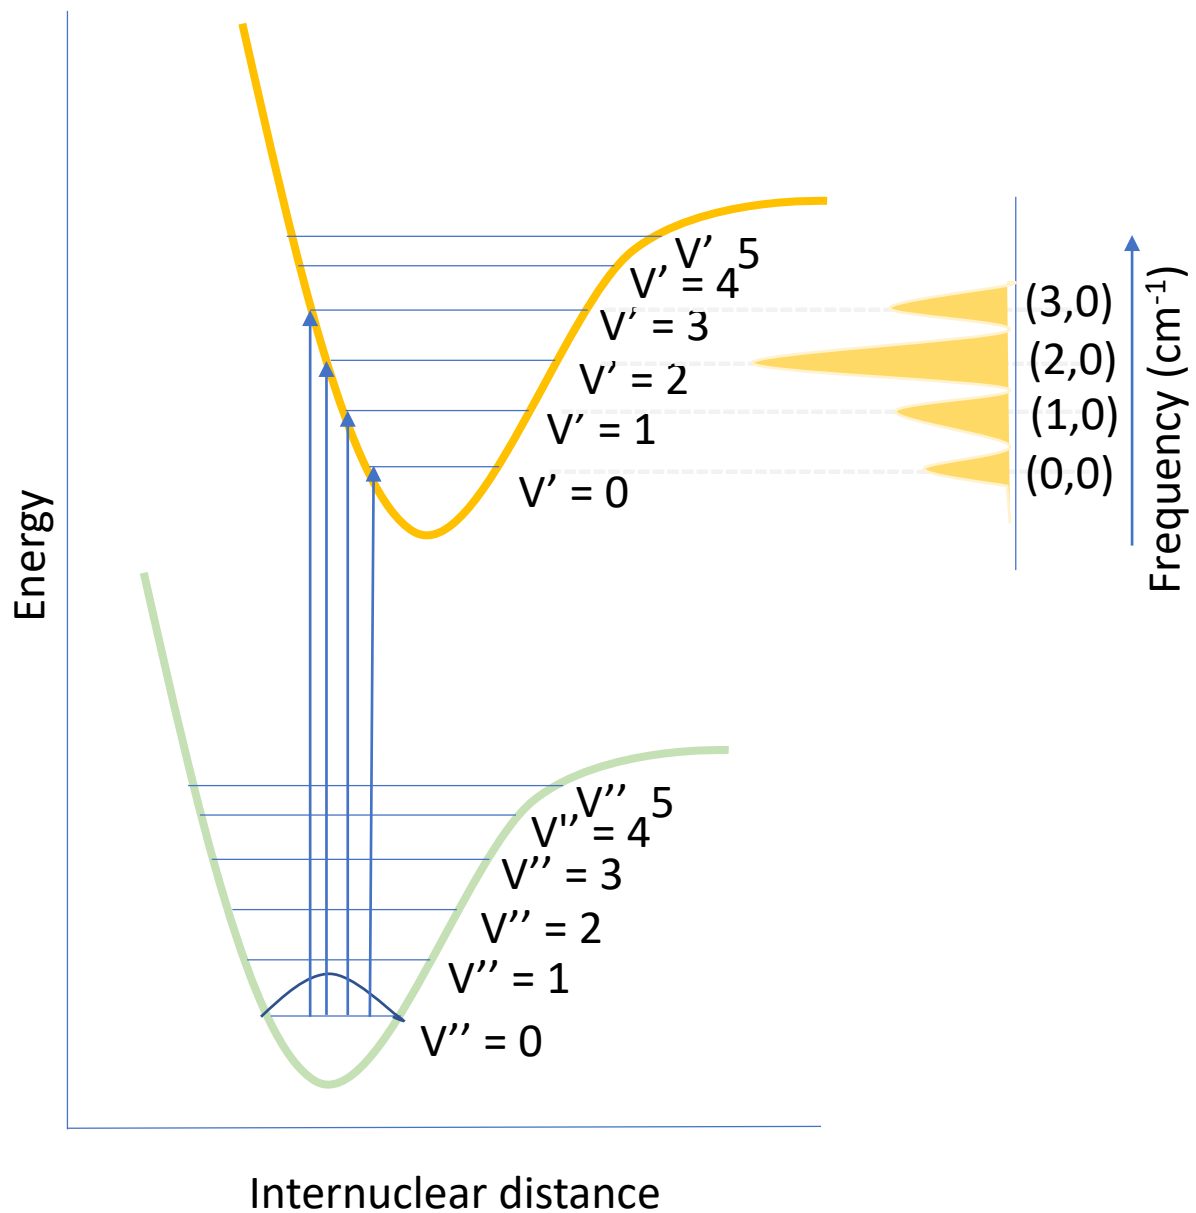

Condition 1: when r_{eq} (ground state) = r_{eq} (excited state)

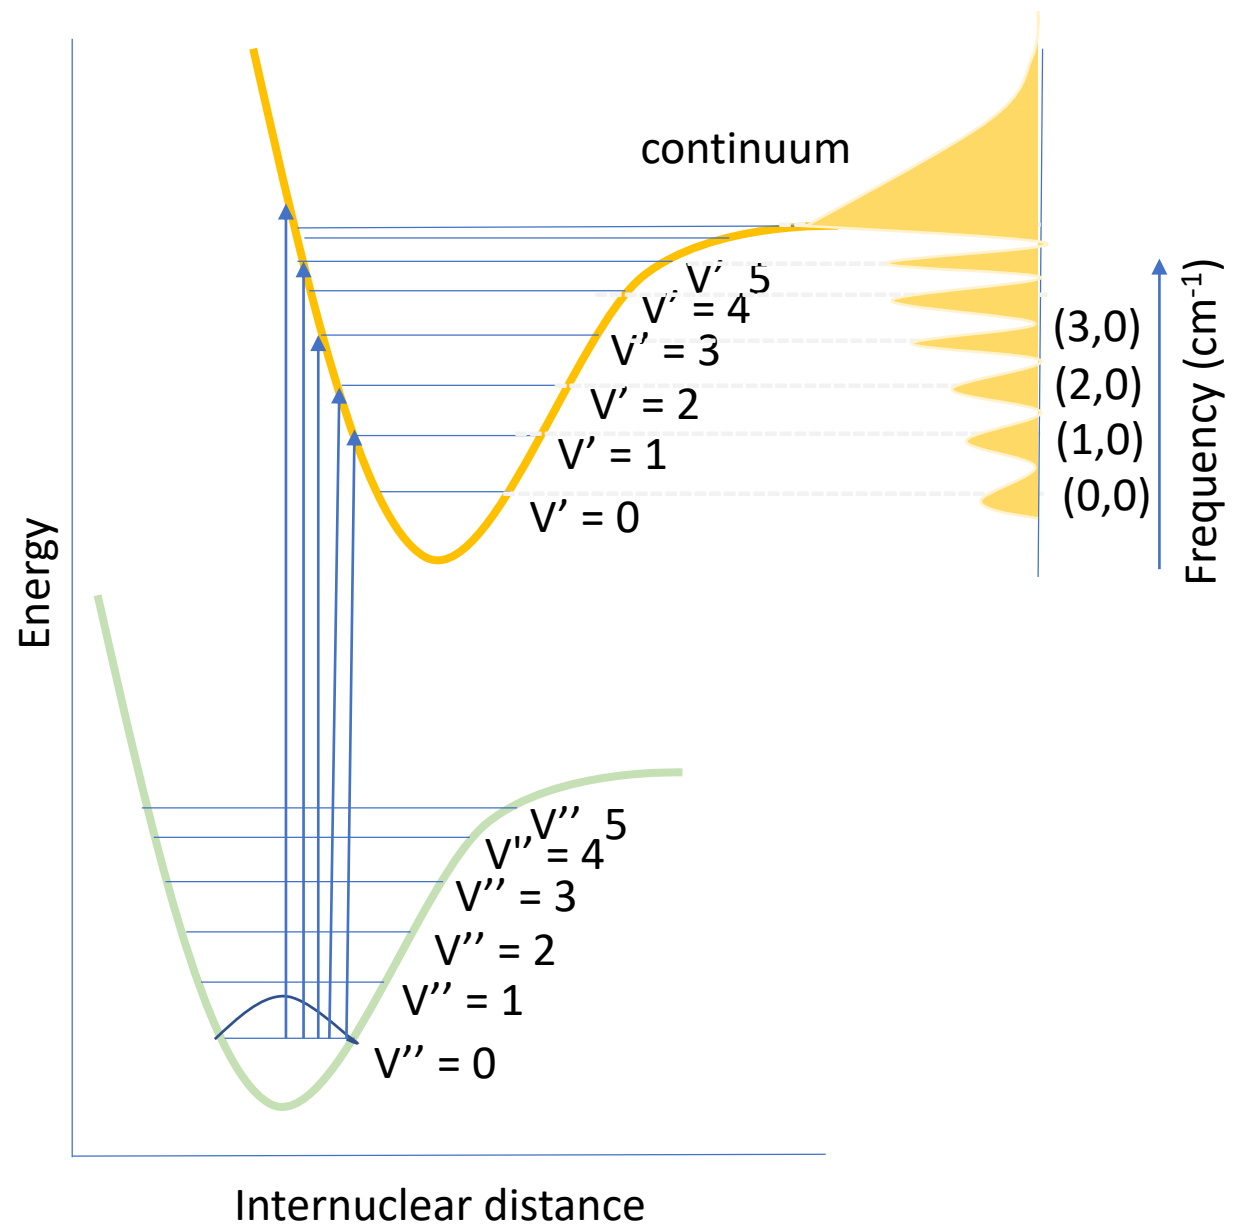

Condition 2: when r_{eq} (ground state) > r_{eq} (excited state)

Condition 3: when r_{eq} (ground state) < r_{eq} (excited state)

Condition 4: when r_{eq} (ground state) \ll r_{eq} (excited state)
